## The Alkanes

**Alkanes** are defined as open-chain ( \_\_\_\_\_ ) hydrocarbons that do not contain any double or triple bonds. Because they contain the maximum number of hydrogen atoms, they are called \_\_\_\_\_ hydrocarbons.

The naming of all organic molecules is based on the naming system for alkanes. Alkanes are named by the number of \_\_\_\_\_ in their \_\_\_\_\_.

Structural formula	Molecular formula	Condensed formula	Stick Diagram	IUPAC name
$\begin{array}{c} \text{H} \\   \\ \text{H}-\text{C}-\text{H} \\   \\ \text{H} \end{array}$			N/A	
$\begin{array}{c} \text{H} \quad \text{H} \\   \quad   \\ \text{H}-\text{C}-\text{C}-\text{H} \\   \quad   \\ \text{H} \quad \text{H} \end{array}$			N/A	
$\begin{array}{c} \text{H} \quad \text{H} \quad \text{H} \\   \quad   \quad   \\ \text{H}-\text{C}-\text{C}-\text{C}-\text{H} \\   \quad   \quad   \\ \text{H} \quad \text{H} \quad \text{H} \end{array}$				
$\begin{array}{c} \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \\   \quad   \quad   \quad   \\ \text{H}-\text{C}-\text{C}-\text{C}-\text{C}-\text{H} \\   \quad   \quad   \quad   \\ \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \end{array}$				
$\begin{array}{c} \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \\   \quad   \quad   \quad   \quad   \\ \text{H}-\text{C}-\text{C}-\text{C}-\text{C}-\text{C}-\text{H} \\   \quad   \quad   \quad   \quad   \\ \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \end{array}$				
$\begin{array}{c} \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \\   \quad   \quad   \quad   \quad   \quad   \\ \text{H}-\text{C}-\text{C}-\text{C}-\text{C}-\text{C}-\text{C}-\text{H} \\   \quad   \quad   \quad   \quad   \quad   \\ \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \end{array}$				

Similarly, a seven-carbon alkane ( $\text{C}_7\text{H}_{16}$ ) is called \_\_\_\_\_

- a eight-carbon alkane ( $\text{C}_8\text{H}_{18}$ ) is called \_\_\_\_\_
- a nine-carbon alkane ( $\text{C}_9\text{H}_{20}$ ) is called \_\_\_\_\_
- a ten-carbon alkane ( $\text{C}_{10}\text{H}_{22}$ ) is called \_\_\_\_\_

**The general molecular formula for an alkane is**

The alkanes are a \_\_\_\_\_ series: a family of hydrocarbons that differ only in the number of \_\_\_\_\_ groups.

The alkanes may also be branched (have side chains). The side chains are called \_\_\_\_\_ and are named according to the number of carbon atoms:

- CH<sub>3</sub> has 1 carbon, it is \_\_\_\_\_
- CH<sub>2</sub>CH<sub>3</sub> has 2 carbons, it is \_\_\_\_\_
- CH<sub>2</sub>CH<sub>2</sub>CH<sub>3</sub> has 3 carbons, it is \_\_\_\_\_
- CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>3</sub> has 4 carbons, it is \_\_\_\_\_
- CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>3</sub> has 5 carbons, it is \_\_\_\_\_
- CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>3</sub> has 6 carbons, it is \_\_\_\_\_

### To name branched chain alkanes:

1. Identify the longest continuous hydrocarbon chain. The number of carbon atoms in this chain determines the base-name of the hydrocarbon.
2. Number the carbon atoms along the main chain so that the side chains (alkyl groups) have the lowest possible position numbers.
3. If there is more than one *type* of side chain, name them in alphabetical order with their position number. Put a hyphen (dash) between the position number and the name of the side chain.
4. If there are two or more of the same side chain, write “diethyl” or “trimethyl”, but name them in alphabetical order according to the name of the side chain (diethyl or trimethyl), not the prefix. Indicate their position numbers, separated by a comma.

Compounds that have the same molecular formulas but different structural formulas are called \_\_\_\_\_ . (“iso” means \_\_\_\_\_ and “mer” means \_\_\_\_\_).

Structural isomers may have very different physical properties, depending on the amount of branching.

Side chains (alkyl groups) can also be branched. You need to know the following:

### To draw hydrocarbons:

eg. Using the example: 3-ethyl-2,2-dimethylpentane

1. Determine the main carbon chain and draw a “skeleton”  
eg. the base name for the hydrocarbon is pentane, so draw \_\_\_ carbons:
2. Use the names and position numbers of the side chains, draw them in  
eg. there is an ethyl group on the third carbon  
there are two methyl groups on the second carbon
3. Fill in the molecule with hydrogen atoms to complete stable octets
4. Double-check your structure by naming it:

## Unit 2, Lesson 01: Introduction to Organic Chemistry and Hydrocarbons

### Homework:

1. Read pages 4 – 9
2. Define: organic compounds.
3. What did Friedrich Wohler discover and why was it significant?
4. On page 10, do questions 1 – 4. On page 11, do questions 1 – 4.
5. All of the following compounds contain carbon. Classify and name them. An ion chart may help.

Compound	Ionic or Covalent	Organic or Inorganic	Name of Compound
CO <sub>2</sub>			
Ca(CN) <sub>2</sub>			
C <sub>3</sub> H <sub>8</sub>			
CH <sub>3</sub> COOH			
KSCN			
Na <sub>4</sub> C			
C <sub>6</sub> H <sub>14</sub>			
SrCO <sub>3</sub>			
C <sub>6</sub> H <sub>12</sub> O <sub>6</sub>			
C <sub>8</sub> H <sub>18</sub>			
CO			

6. Why are the straight chain alkanes called a “homologous series”?
7. What is the general formula for the molecular formula of alkanes? What does “n” represent?
8. Write the molecular formulas of the alkanes with:
  - a) 15 carbon atoms
  - b) 20 carbon atoms
  - c) 72 hydrogen atoms
9. Is C<sub>18</sub>H<sub>36</sub> an alkane? Explain.
10. Write the molecular formula for dodecane (12 carbon atoms).
11. What is meant by a “saturated” hydrocarbon?
12. What is the significance of the mnemonic “monkeys eat peeled bananas”?
13. Are hydrocarbons polar or pure covalent compounds? Justify your answer with reference to electronegativity values. Based on your answer, predict four physical properties of hydrocarbons.
14. What is meant by an “alkyl group”?
15. What would you name an *alkyl group* that contains 5 carbon atoms?
16. Define structural isomer. Draw four structural isomers of hexane. Name each isomer.
17. Draw the condensed structural formulas for the following:
  - a) 3,4-dimethyl hexane
  - b) 3-ethyl-3-methyl pentane
  - c) 4-ethyl-2-methyl hexane
  - d) 3,3-diethyl-4,5-dimethyl heptane
  - e) 2,3-dimethyl-4-propyl octane

18. For each of the following organic molecules:

- write its IUPAC name
- write its molecular formula
- identify all molecules which are structural isomers

$\begin{array}{c} \text{H} \quad \text{H} \quad \text{H} \\   \quad   \quad   \\ \text{H}-\text{C}-\text{C}-\text{C}-\text{H} \\   \quad   \quad   \\ \text{H} \quad \text{H} \quad \text{H} \end{array}$	$\begin{array}{c} \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \\   \quad   \quad   \quad   \quad   \quad   \\ \text{H}-\text{C}-\text{C}-\text{C}-\text{C}-\text{C}-\text{C}-\text{H} \\   \quad   \quad   \quad   \quad   \quad   \\ \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \end{array}$	$\text{CH}_3-\text{CH}_2-\text{CH}_2-\text{CH}_3$
		$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$
$\begin{array}{c} \text{H} \\   \\ \text{CH}_3-\text{C}-\text{CH}_2-\text{CH}_3 \\   \\ \text{CH}_3 \end{array}$	$\begin{array}{c} \text{CH}_3 \\   \\ \text{CH}_3-\text{C}-\text{CH}_3 \\   \\ \text{CH}_3 \end{array}$	$\begin{array}{c} \text{CH}_3 \\   \\ \text{CH}_3-\text{C}-\text{CH}_2-\text{CH}_3 \\   \\ \text{CH}_3 \end{array}$

		$\begin{array}{c} \text{CH}_3 \\   \\ \text{CH}_3-\text{CH}-\text{C}-\text{CH}_2-\text{CH}_3 \\   \quad   \\ \text{CH}_3 \quad \text{CH}_2-\text{CH}_2-\text{CH}_3 \end{array}$

## Unit 2, Lesson 02: The Alkenes and Alkynes

**Alkenes** are defined as open-chain hydrocarbons that contain at least one \_\_\_\_\_ (\_\_\_\_\_).

**Alkynes** are defined as open-chain hydrocarbons that contain at least one \_\_\_\_\_ (\_\_\_\_\_).

Because they contain less than the maximum number of hydrogen atoms, they are called “\_\_\_\_\_” hydrocarbons.

Naming for alkenes and alkynes is generally the same as for the alkanes, but with two changes:

- the position of the double or triple bond(s) is included in the name, and
- the suffix (ending) of the name is changed to \_\_\_\_\_ for alkenes or \_\_\_\_\_ for alkynes

Structural formula	Molecular formula	Condensed formula	Stick diagram	IUPAC name
$\begin{array}{c} \text{H} & & \text{H} \\ & \diagdown & / \\ & \text{C}=\text{C} & \\ & / & \diagdown \\ \text{H} & & \text{H} \end{array}$			N/A	
$\begin{array}{c} \text{H} & & \text{CH}_3 \\ & \diagdown & / \\ & \text{C}=\text{C} & \\ & / & \diagdown \\ \text{H} & & \text{H} \end{array}$				
$\begin{array}{c} \text{H} & & \text{CH}_2\text{CH}_3 \\ & \diagdown & / \\ & \text{C}=\text{C} & \\ & / & \diagdown \\ \text{H} & & \text{H} \end{array}$				
$\begin{array}{c} \text{CH}_3 & & \text{CH}_3 \\ & \diagdown & / \\ & \text{C}=\text{C} & \\ & / & \diagdown \\ \text{H} & & \text{H} \end{array}$				

**Note:**

- For the first two examples, the naming rules require that double bond will be found on the \_\_\_\_\_ carbon. Because the position of the double bond is known, no position number is needed in the name.
- For the second two examples, the double bond can be found in different positions. These molecules are \_\_\_\_\_ of each other (they have the same \_\_\_\_\_ formulas but different structural formulas). The position of the double bond is indicated with a position number.

Similarly, a five-carbon alkene (C<sub>5</sub>H<sub>10</sub>) is called \_\_\_\_\_

- a six-carbon alkene (C<sub>6</sub>H<sub>12</sub>) is called \_\_\_\_\_
- a seven-carbon alkene (C<sub>7</sub>H<sub>14</sub>) is called \_\_\_\_\_
- a eight-carbon alkene (C<sub>8</sub>H<sub>16</sub>) is called \_\_\_\_\_

**The general molecular formula for an alkene is**

The alkenes are a **homologous series**: a family of hydrocarbons that differ only in the # of \_\_\_\_\_ groups.

If an alkene contains only one double bond, it is \_\_\_\_\_ (mono means “one”)

If an alkene contains two or more double bonds, it is \_\_\_\_\_ (poly means “many”)

- the name of poly-unsaturated alkenes includes the position numbers of all double bonds. The suffix at the end of the base name is changed to indicate the number of double bonds

eg. a six carbon chain with double bonds on C-1 and C-3 would be named \_\_\_\_\_

To name alkenes:

1. Identify the longest continuous hydrocarbon chain that contains the double bond(s). The number of carbon atoms in this chain determines the base-name of the hydrocarbon.
2. The double bond gets priority in naming- the carbon chain is numbered in the direction that will give the double bond the lowest possible number (then number any side chains accordingly).
3. If the double bond is the same distance from both ends, number in the direction that will give the side chains the lowest overall position numbers.
4. The *suffix* of the base name tells us how many double bonds there are:
  - If there is one double bond, the suffix of the base name is "...\_\_\_\_\_"
  - If there are two double bonds, the suffix of the base name is "...\_\_\_\_\_"
  - If there are three double bonds, the suffix of the parent name is "...\_\_\_\_\_ " etc
5. Use the same naming rules for side chains (alkyl groups) that were discussed for the alkanes. Combine the numbers and names of all side chains with the parent name to form one word. Use hyphens to separate numbers from names. Use commas to separate numbers.

### Geometric Isomers of Alkenes (cis-trans)

Atoms can rotate around a single bond, so all positions around a single bond are \_\_\_\_\_ . Alkanes do not form geometric isomers.

Atoms can **not** rotate around a double bond. Double bonds "lock" the molecule into a certain arrangement.

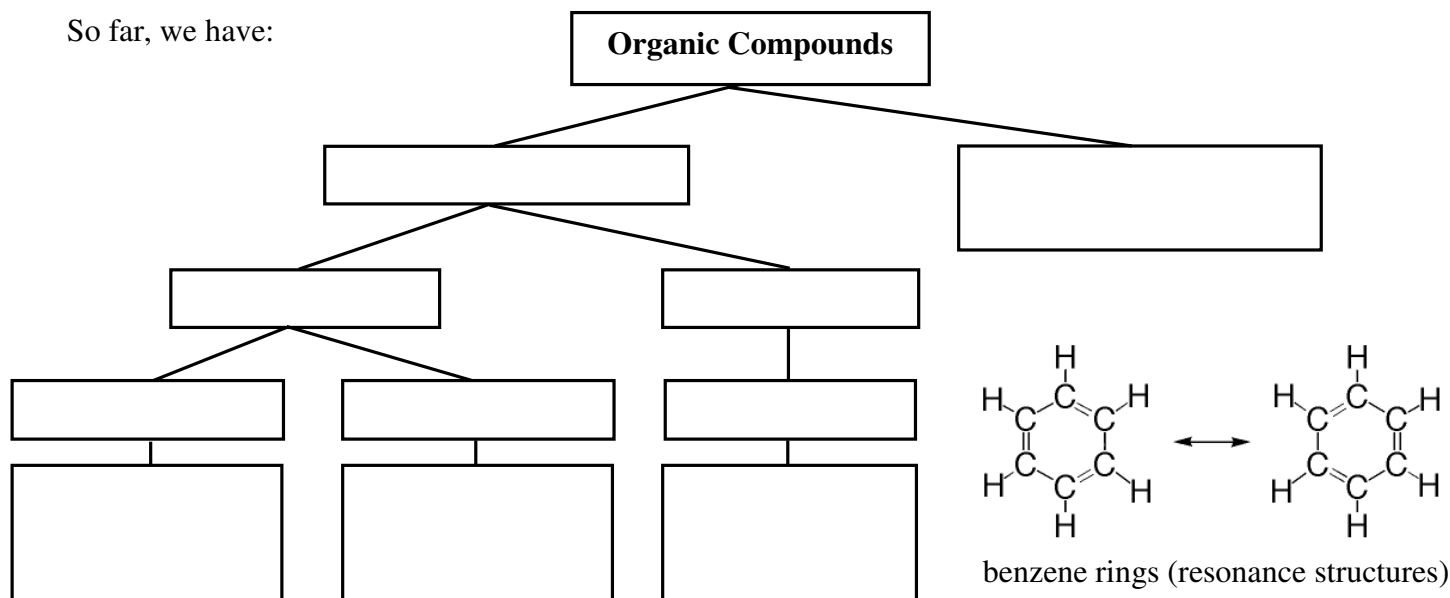

If the largest side chains of an alkene are "locked into" the same side of the double bond, then the molecule is called the "\_\_\_\_\_" isomer. Most molecules in living systems are "\_\_\_\_\_" isomers.

If the largest side chains of an alkene are "locked into" opposite sides of the double bond, then the molecule is called the "\_\_\_\_\_" isomer.

You can only identify cis/trans isomers if you are given an expanded structural formula.

So far, we have:

### Unit 2, Lesson 03: Cyclic and Aromatic Hydrocarbons

**Aliphatic hydrocarbons** are hydrocarbons that do not contain a \_\_\_\_\_

- include both acyclic (straight chain) and “cyclic” hydrocarbons

**Cycloalkanes** are aliphatic, saturated hydrocarbons that are joined in a ring-structure

- formation of a ring structure is called \_\_\_\_\_
- commonly drawn using stick diagrams, each “corner” represents one carbon atom
- have the general molecular formula \_\_\_\_\_

**To name a cycloalkane:**

1. the number of carbon atoms in the ring structure determines the base name of the molecule. The name begins with \_\_\_\_\_:  
eg. a seven carbon ring is \_\_\_\_\_, a nine carbon ring is \_\_\_\_\_
2. name the side chains attached to the ring structure
  - if there is only one side chain present, no position number is needed because all of the carbon atoms in the ring are considered to be equivalent
  - if there is more than one side chain present, number the carbons in the ring according to the priority of the side chain. The longest side chain has the highest priority so it should get the \_\_\_\_\_ number. Number the ring in whichever direction will give the lowest numbers overall.

**Cycloalkenes** are aliphatic hydrocarbons that are joined in a ring-structure and contain at least one \_\_\_\_\_ (but are not \_\_\_\_\_)

- cycloalkenes are named according to the number of carbon atoms in the ring structure and are named “cyclo\_\_ene”
- the carbon with the double bond is **ALWAYS** position number \_\_\_\_\_. When there is only one double bond, the position number does not need to be included in the name (it is on \_\_\_\_\_)
- positions of side chains are indicated relative to the double bond (\_\_\_\_\_). Number the ring in whichever direction will give the side chains the lowest position numbers overall
- cycloalkenes with two double bonds are named “cyclo\_\_diene”. Position numbers for both double bonds must be given if a cycloalkene has more than one double bond

**Aromatic Hydrocarbons** are organic molecules that contain a \_\_\_\_\_ ring structure

- benzene compounds often have \_\_\_\_\_ or “aromas”, which is why they are called “aromatic”
- benzene is a \_\_\_\_-carbon ring that contains \_\_\_\_ double bonds, its molecular formula is \_\_\_\_\_
- the C – C bond length half-way between the length of a single and double bond (\_\_\_\_\_)
- because of the double bonds, it forms a \_\_\_\_\_. The electrons in the double bonds move rapidly in an “\_\_\_\_\_” above and below the molecule
- the molecule is \_\_\_\_\_ (planar) and it is an extremely stable structure
- the benzene ring can be represented many ways:

or

or

the circle represents the “electron cloud” resonance structures

The hydrogen atoms on the benzene ring can be replaced with other groups, including alkyl side chains, hydroxyl groups, halogens and many others.

To name an aromatic compound using the IUPAC system, follow the same rules for cycloalkanes, but use \_\_\_\_\_ as the base name.

When there are two side chains attached to a benzene ring, the position of the side chains relative to one another can be indicated either using position numbers or using an older system:

- If the side chains are on C – 1 and C – 2, then the prefix \_\_\_\_\_ can be used
- If the side chains are on C – 1 and C – 3, then the prefix \_\_\_\_\_ can be used
- If the side chains are on C – 1 and C – 4, then the prefix \_\_\_\_\_ can be used

### Physical Properties of Hydrocarbons

Hydrocarbons contain only carbon and hydrogen atoms, with no lone pairs, so they are all \_\_\_\_\_:

- they have only \_\_\_\_\_ between molecules, which are \_\_\_\_\_
  - they are \_\_\_\_\_ in water (which is \_\_\_\_\_)
  - they are soluble in \_\_\_\_\_ solvents (such as \_\_\_\_\_, \_\_\_\_\_)
1. As the length of the carbon chain increases, the melting and boiling points \_\_\_\_\_ because the London dispersion forces between molecules \_\_\_\_\_  
 $C_1$ - $C_4$  alkanes are \_\_\_\_\_     $C_5$ - $C_{16}$  alkanes are \_\_\_\_\_     $C_{16}$ - $C_{24}$  are \_\_\_\_\_
  2. As branching increases, melting and boiling points \_\_\_\_\_ because the molecules can not line up nicely beside one another, so LDFs \_\_\_\_\_
  3. As the number of double bonds increases, the melting and boiling points \_\_\_\_\_
    - double bonds introduce a \_\_\_\_\_ in the carbon chain that makes the molecule “\_\_\_\_\_” because of the “kinks”, alkene molecules do not pack together as well as alkanes, so they have lower London dispersion forces and therefore, \_\_\_\_\_ melting and boiling points than alkanes

## Unit 2, Lessons 04 and 05: Reactions of Hydrocarbons

### Summary of reactions of hydrocarbons:

1. all hydrocarbons undergo combustion reactions
2. alkanes are the least reactive and can undergo **substitution** reactions with HF, Cl<sub>2</sub> and Br<sub>2</sub>
3. aromatics are in between alkanes and alkenes in reactivity and can undergo **substitution** reactions with halogens in the presence of FeBr<sub>3</sub> catalyst
4. alkenes are very reactive and can undergo **addition** reactions as follows:

### General addition reaction:

a) addition of halogens (\_\_\_\_\_):

b) addition of hydrogen (\_\_\_\_\_):

c) addition of hydrogen halides (HCl, HF, HBr, HI). Follows **Markovnikov's Rule**: when hydrogen halides or water are added across a double bond, the hydrogen atom is added to whichever carbon atom has the \_\_\_\_\_ hydrogen atoms already ("the \_\_\_\_\_ get \_\_\_\_\_")

d) addition of water (\_\_\_\_\_, follows Markovnikov's Rule):

e) slow oxidation with an oxidizing agent, [O], such as KMnO<sub>4</sub>:

## Unit 2, Lessons 04 and 05: Homework on Chemical Reactions of Hydrocarbons

### Homework:

1. Read pages 57 – 60 and 65 – 70.
2. On page 68, do questions 7 and 8
3. Draw the products of the following reactions. Use Markovnikov's Rule where applicable.

4. Which of the following pairs of molecules will have a higher melting point? Explain for each pair.

5. Write the balanced chemical reactions for the combustion of the following hydrocarbons. Include the states of all reactants and products.

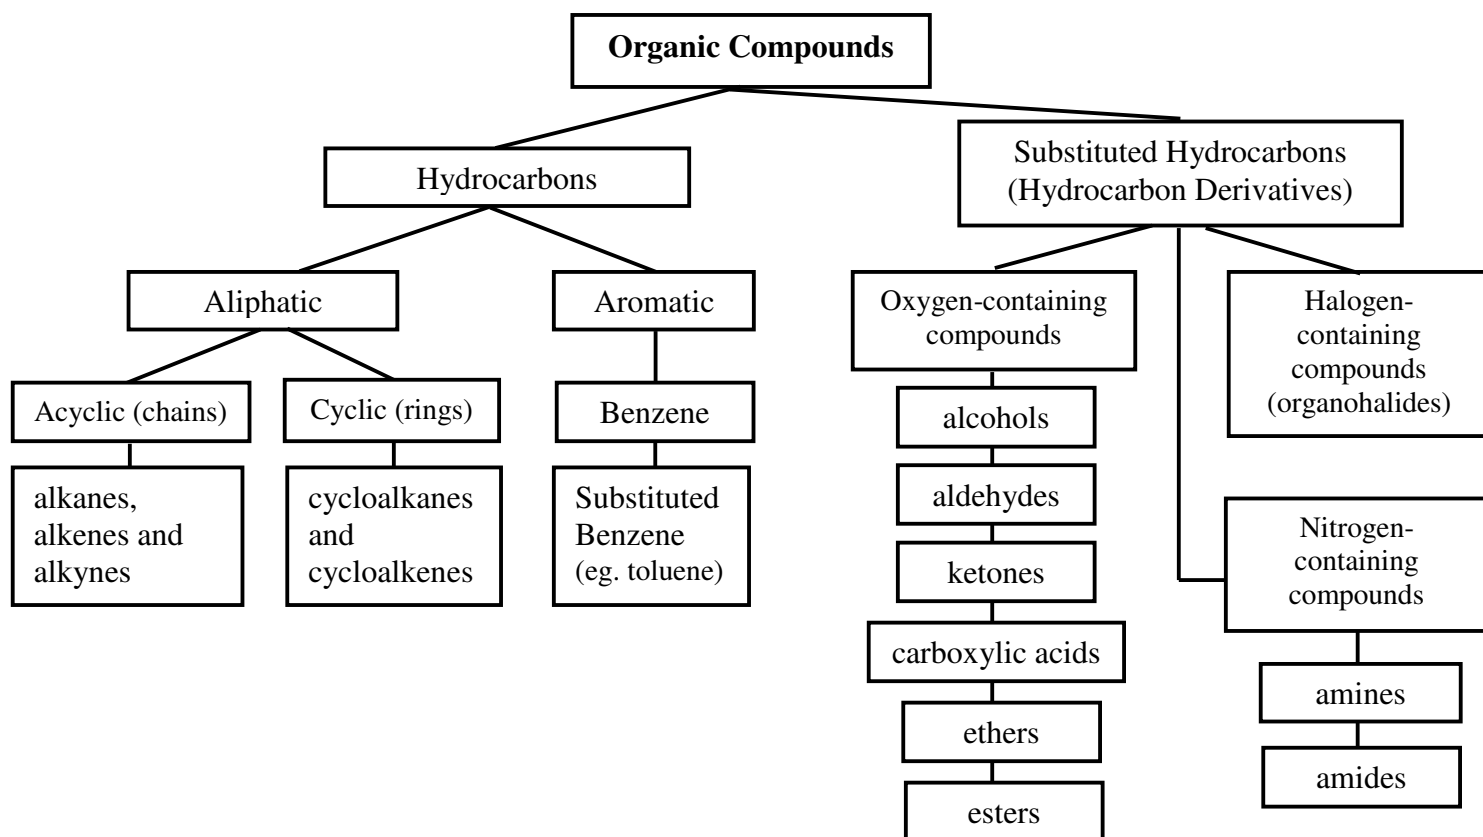

- octane
- 2-pentene
- cyclopropane
- 3-heptyne

6. Arrange the following compounds in order of increasing reactivity. Explain why you put them in this order:

- cyclohexene
- cyclohexane
- benzene

7. Describe two different chemical tests you could perform to distinguish between butane and 1-butene. What are three different physical properties of these substances that could be used to distinguish them?

## Unit 2, Lesson 08: Classification of Organic Compounds

### Definitions

<b>Hydrocarbons:</b> molecules that contain only carbon and hydrogen	<b>Substituted Hydrocarbons (Hydrocarbon Derivatives):</b> contain carbon, hydrogen and at least one other element (O, N, S or a halogen)
<b>Aliphatic:</b> hydrocarbons that do not contain a benzene ring	<b>Alcohols:</b> substituted hydrocarbons that contain a hydroxyl (-OH) functional group (R - OH)
<b>Aromatic:</b> hydrocarbons that contain a benzene ring	<b>Aldehydes:</b> substituted hydrocarbons that contain a C = O group on a terminal carbon (R = CHO)
<b>Acyclic:</b> (the prefix "a" means without) open chain hydrocarbons that do not contain a ring structure	<b>Ketones:</b> substituted hydrocarbons that contain a C = O group on a non-terminal carbon (R - CO - R')
<b>Cyclic:</b> hydrocarbons that contain a ring structure (but not a benzene ring)	<b>Carboxylic Acids:</b> substituted hydrocarbons that contain a -COOH (carboxyl) group (R - COOH)
<b>Alkanes:</b> open chain hydrocarbons that do not have any double or triple bonds; they are saturated	<b>Ethers:</b> substituted hydrocarbons that contain a C - O - C functional group (R - O - R')
<b>Alkenes:</b> open chain hydrocarbons that contain at least one carbon-carbon double bond; they are unsaturated	<b>Esters:</b> substituted hydrocarbons that contain a - COO functional group (R - COO- R')
<b>Alkynes:</b> open chain hydrocarbons that contain at least one carbon-carbon triple bond; unsaturated	<b>Amines:</b> substituted hydrocarbons that contain a - NH <sub>2</sub> (amine) functional group (R - NH <sub>2</sub> )
<b>Cycloalkanes:</b> saturated hydrocarbons that contain a carbon ring structure, but not a benzene ring	<b>Amides:</b> substituted hydrocarbons that contain a - CON functional group (R - CO - N - R')
<b>Cycloalkenes:</b> alkenes that contain a carbon ring structure, but not a benzene ring	<b>Organohalides:</b> substituted hydrocarbons that contain one or more halogen atoms (eg. R - Cl or R - Br)

## Unit 2, Lessons 08 and 09: Substituted Hydrocarbons

### 1. Alkyl Halides (also known as \_\_\_\_\_)

- contain one or more halogen atoms (\_\_\_\_\_) attached to an alkyl (hydrocarbon) chain
- abbreviated \_\_\_\_\_, where \_\_\_\_\_ is a halogen atom

### Naming Rules for Alkyl Halides:

- number the alkyl chain so that the halogen atoms have the lowest possible position numbers
- name the halogen atoms in alphabetical order. Change the ending of the halogen from \_\_\_\_\_ to “\_\_\_\_\_” (eg. bromine becomes \_\_\_\_\_, chlorine becomes \_\_\_\_\_, iodine becomes \_\_\_\_\_)
- indicate how many of each type of halogen are present with the prefixes \_\_\_\_\_
- if a molecule also has alkyl side chains (methyl, ethyl etc), name these side chains in alphabetical order along with the halogens, include their position numbers
- name the parent alkyl molecule
- if the molecule is an alkene or alkyne, the double or triple bond gets \_\_\_\_\_ in naming. The multiple bond is assigned the \_\_\_\_\_ possible position number

### Physical Properties of Alkyl Halides:

- the addition of halogens makes the molecule \_\_\_\_\_, but the degree of polarity depends on which halogen is present
- the F – C bond is significantly \_\_\_\_\_, so fluoro-hydrocarbons are \_\_\_\_\_ in water and their melting and boiling points are significantly \_\_\_\_\_ than their parent alkane
- CFCs (\_\_\_\_\_) such as \_\_\_\_\_ destroy \_\_\_\_\_
- other alkyl halides (chloro, bromo and iodo) are only \_\_\_\_\_, so they are only \_\_\_\_\_ miscible in water and their melting and boiling points are only \_\_\_\_\_ than their parent alkane
- because they are polar, many alkyl halides are \_\_\_\_\_ at SATP (small molecules are \_\_\_\_\_)
- the longer the alkyl chain (“R”), the \_\_\_\_\_ the solubility in water

## 2. Alcohols

- contain one or more \_\_\_\_\_ (\_\_\_\_\_) functional groups
- abbreviated \_\_\_\_\_

Alcohols may be classified as primary ( ), secondary ( ) or tertiary ( ) alcohols:

A primary (1°) alcohol:	A secondary (2°) alcohol:	A tertiary (3°) alcohol:
$\text{CH}_3 - \text{CH}_2 - \text{CH}_2 - \text{CH}_2 - \text{OH}$	$\begin{array}{c} \text{H} \\   \\ \text{CH}_3 - \text{C} - \text{CH}_2 - \text{CH}_3 \\   \\ \text{OH} \end{array}$	$\begin{array}{c} \text{OH} \\   \\ \text{CH}_3 - \text{C} - \text{CH}_3 \\   \\ \text{CH}_3 \end{array}$
- OH group is attached to a carbon that is attached to _____ other carbon atom	- OH group is attached to a carbon that is attached to _____ other carbon atoms	- OH group is attached to a carbon that is attached to _____ other carbon atoms

### Naming Rules for Alcohols:

- the base name is determined by the longest carbon chain that includes the \_\_\_\_\_ group
- remove the “e” from the hydrocarbon base name and add the suffix \_\_\_\_\_ (\_\_\_\_\_)
- number the alkyl chain to give the hydroxyl group(s) the \_\_\_\_\_ possible position numbers
- name any halogen atoms and alkyl side chains in alphabetical order, include their position numbers
- indicate the position number of the - OH group(s), except for cyclic structures with only one - OH
- if there are two hydroxyl groups, add the suffix \_\_\_\_\_ to the end of the alkane base name
- if there are three hydroxyl groups, add the suffix \_\_\_\_\_ to the end of the alkane base name

### Physical Properties of Alcohols:

- the - OH group is \_\_\_\_\_ and is capable of \_\_\_\_\_, so:
  - alcohols are \_\_\_\_\_ in water
  - most alcohols are \_\_\_\_\_ at SATP
  - alcohols have relatively \_\_\_\_\_ melting points
- the longer the alkyl chain (“R”), the \_\_\_\_\_ the solubility in water

### 3. Aldehydes

- have a \_\_\_\_\_ group (\_\_\_\_\_) on a primary carbon (the \_\_\_\_\_ carbon of a carbon chain)
- abbreviated \_\_\_\_\_
- do not confuse aldehydes (\_\_\_\_\_) with alcohols (\_\_\_\_\_)

e.g.

### Naming Rules for Aldehydes:

- the aldehyde group is always the \_\_\_\_\_ carbon, so \_\_\_\_\_ position number is needed
- the base name is determined by the longest carbon chain that begins with the \_\_\_\_\_ group
- remove the “e” from the base name; add the suffix \_\_\_\_\_ (\_\_\_\_\_)
- the chain numbering starts from **and includes** the CHO carbon atom of the aldehyde group
- name any side chains in alphabetical order and give their position numbers

### 4. Ketones

- a ketone is an organic molecule that has a \_\_\_\_\_ group (\_\_\_\_\_) on a \_\_\_\_\_ (non-terminal) carbon of a carbon chain
- abbreviated:

e.g.

### Naming Rules for Ketones:

- the base name is determined by the longest carbon chain that contains the carbonyl (\_\_\_\_\_) group
- remove the “e” from the base name; add the suffix \_\_\_\_\_ (\_\_\_\_\_)
- number the carbon chain so that the carbonyl group has the \_\_\_\_\_ possible position number
- if the location of the carbonyl group is ambiguous, identify its position number
- name any other side chains in alphabetical order, include their position numbers

### Physical Properties of Aldehydes and Ketones:

- the  $C = O$  group is \_\_\_\_\_, but there is no \_\_\_\_\_, so:
  - aldehydes and ketones are generally \_\_\_\_\_ in water
  - many aldehydes and ketones are \_\_\_\_\_ at SATP
  - aldehydes and ketones have relatively \_\_\_\_\_ melting and boiling points
- the longer the alkyl chain, the \_\_\_\_\_ the solubility in water

## 5. Carboxylic Acids

- a carboxylic acid is an organic molecule that has one or more \_\_\_\_\_ groups on an alkyl chain
- abbreviated \_\_\_\_\_

eg.

### Naming Rules for Carboxylic Acids with one Carboxyl Group:

- the base name is determined by the longest carbon chain that begins with the \_\_\_\_\_
- remove the “e” from the base name; add the suffix \_\_\_\_\_
- the carboxyl group (- COOH) is always \_\_\_\_\_, so \_\_\_\_\_ position number is needed
- the chain numbering starts from and includes the COOH carbon atom of the carboxyl group
- name any side chains in alphabetical order and give their position numbers

### Physical Properties of Carboxylic Acids:

- the carboxyl group is \_\_\_\_\_ and capable of \_\_\_\_\_, so:
  - carboxylic acids are very \_\_\_\_\_ (\_\_\_\_\_) in water
  - are \_\_\_\_\_ or soft \_\_\_\_\_ at SATP
  - have relatively \_\_\_\_\_ melting and boiling points
- the longer the alkyl chain, the \_\_\_\_\_ the solubility in water

## 6. Amines

- an amine is an organic molecule that contains at least one \_\_\_\_\_ (\_\_\_\_\_)
- abbreviated \_\_\_\_\_
- for the purposes of this course, we will discuss only primary amines

### Naming Rules for Primary Amines:

- are very similar to the naming rules for alcohols
- the base name is determined by the longest carbon chain that contains the \_\_\_\_\_ group
- remove the “e” from the base name; add the suffix \_\_\_\_\_
- include a position number to indicate the location of the amine group on the alkyl chain
- if there are other side chains or groups, name them in alphabetical order and indicate their position numbers

### Physical Properties of Amines:

- primary amines are \_\_\_\_\_ and capable of \_\_\_\_\_, so
  - amines are generally \_\_\_\_\_ in water
  - are \_\_\_\_\_ at SATP
  - have relatively \_\_\_\_\_ melting and boiling points (but not as high as \_\_\_\_\_)
  - amines often have distinctive \_\_\_\_\_ odours
- the longer the alkyl chain, the \_\_\_\_\_ the solubility in water

**FYI:** In biology, you have discussed amino acids. These are organic molecules that have at least one amine and at least one carboxylic acid group. They are known by their common (not IUPAC) names:

eg.

alanine

aspartate  
(combined with  
phenylalanine to make  
aspartame or “Nutrasweet”)

glutamate  
(part of MSG)

phenylalanine  
(children with  
PKU can not  
break this down)

## Unit 2, Lesson 10: Reactions of Alcohols

**Functional groups** are groups of atoms that are chemically bonded together in a specific arrangement.

- functional groups give a molecule predictable \_\_\_\_\_ and \_\_\_\_\_ properties
- the alcohol functional group (\_\_\_\_\_) undergoes many types of reactions:

### 1. Combustion reactions (rapid oxidation) of alcohols:

- produce \_\_\_\_\_ and \_\_\_\_\_

### 2. Substitution reactions of alcohols:

- the -OH group is \_\_\_\_\_ by another functional group (eg. a halogen, amine or nitro group)

### 3. Elimination reactions of alcohols:

- the reverse of \_\_\_\_\_ reactions
- \_\_\_\_\_ is removed and a \_\_\_\_\_ is formed
- because water is removed, these reactions can also be classified as \_\_\_\_\_ reactions
- Markovnikov's Rule applies in reverse: "the \_\_\_\_\_ get \_\_\_\_\_". The carbon atom with the \_\_\_\_\_ H atoms that is adjacent to the -OH group will \_\_\_\_\_ its H atom to form the double bond

#### 4. Oxidation reactions of alcohols with an oxidizing agent [O]

- oxidation has occurred if:
  - i) a carbon atom forms \_\_\_\_\_ bonds with oxygen atoms (including the formation of \_\_\_\_\_ double bonds, this counts as a carbon atom with \_\_\_\_\_ bonds to oxygen)
  - ii) a carbon atom ends up with \_\_\_\_\_ bonds to hydrogen atoms
- reduction has occurred if:
  - i) a carbon atom forms \_\_\_\_\_ bonds with oxygen atoms
  - ii) a carbon atom ends up with \_\_\_\_\_ bonds to H atoms
- each class of alcohol ( \_\_\_\_\_ ) undergoes different oxidation reactions
- common oxidizing agents \_\_\_\_\_ include: \_\_\_\_\_
- you do not need to balance these reactions

##### a) Oxidation of primary alcohols:

- the -OH group is attached to a carbon atom that is attached to \_\_\_\_\_ other C atom
- the reaction occurs in two steps:

##### b) Oxidation of secondary alcohols:

- the -OH group is attached to a carbon atom that is attached to \_\_\_\_\_ other C atoms
- occurs in only one step:

##### c) Oxidation of tertiary alcohols:

- the -OH group is attached to a carbon atom that is attached to \_\_\_\_\_ other C atoms
- \_\_\_\_\_ oxidation reaction occurs

## 5. Condensation Reactions:

- condensation reactions occur when \_\_\_\_\_ molecules combine to form \_\_\_\_\_
- a molecule of \_\_\_\_\_ is released, so these reactions are also \_\_\_\_\_ reactions

### a) Formation of Ethers

- two \_\_\_\_\_ molecules condense (combine) to form an \_\_\_\_\_ and a molecule of \_\_\_\_\_
- the ether functional group is drawn structurally as:

### Naming Rules for Ethers:

- look at the two alkyl (R) groups that are attached to the oxygen atom
- the base name for the molecule comes from the \_\_\_\_\_ R group
- treat the shorter alkyl chain and the oxygen atom as one group. Change the “yl” suffix of the alkyl group to “\_\_\_\_\_” (methyl becomes \_\_\_\_\_, ethyl to \_\_\_\_\_, propyl to \_\_\_\_\_)
- treat the ether group as just another side chain on the larger alkyl chain. Name it, along with any other side chains, in alphabetical order. Include position numbers as needed.
- the ether group has the \_\_\_\_\_ priority as a alkyl side chain

### Physical Properties of Ethers:

- the C – O – C group bent, so it is \_\_\_\_\_, but there is no \_\_\_\_\_ so:
  - ethers are generally \_\_\_\_\_ in water
  - many ethers are \_\_\_\_\_ or \_\_\_\_\_ at SATP
  - because the O atom is “buried” in the middle of the molecule, ethers are only slightly more polar than the alkanes, so they have very \_\_\_\_\_ melting and boiling points
- the longer the alkyl chains, the \_\_\_\_\_ the solubility in water

## 5. Condensation Reactions:

### b) Formation of Esters

- an \_\_\_\_\_ and a \_\_\_\_\_ condense (combine) to form an \_\_\_\_\_
- a molecule of \_\_\_\_\_ is released, so these reactions are also \_\_\_\_\_ reactions
- the ester functional group is drawn structurally as:

or  $\text{R}-\text{COO}-\text{R}'$  where R and R' are alkyl groups  
(R could be hydrogen in the case of methanoic acid)

### Naming Rules for Esters:

1. identify the carboxylic acid portion of the molecule; this contains the \_\_\_\_\_ group
2. name the carboxylic acid according to the number of carbons (including the C=O carbon). Change the ending of the carboxylic acid from "oic acid" to "\_\_\_\_\_". The "oate" suffix indicates an \_\_\_\_\_.
3. identify the alkyl group that is attached to the oxygen atom. Name this alkyl group.
4. combine the names of the alkyl group and the carboxylic acid (ending in "oate"). The name of the alkyl group comes first and is separated from the second word by a space.

### Physical Properties of Esters:

- the C-O-C and C=O groups are \_\_\_\_\_, but there is no \_\_\_\_\_ so:
  - esters are generally \_\_\_\_\_ in water
  - many esters are \_\_\_\_\_ at SATP
  - because the C=O (carbonyl) group is exposed, the melting and boiling points of esters are slightly higher than the corresponding ether
  - many esters have distinctive \_\_\_\_\_ odours and are used for flavourings
- the longer the alkyl chains, the \_\_\_\_\_ the solubility in water

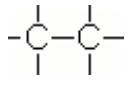

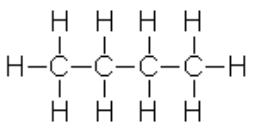

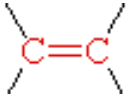

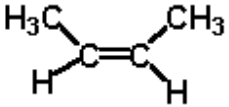

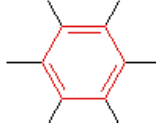

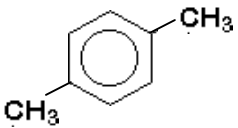

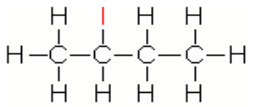

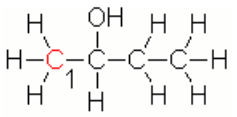

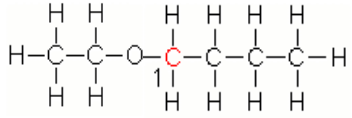

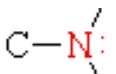

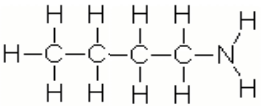

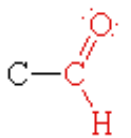

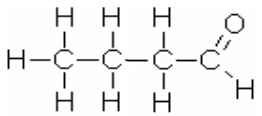

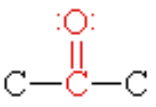

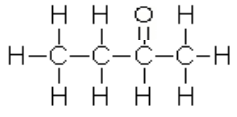

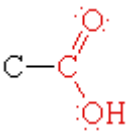

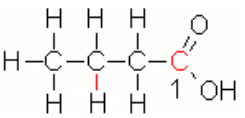

**Unit 2, Lesson 10: Summary of Reactions of Alcohols**

Reactants and/or Reaction Conditions	Products	Type of Reaction	How to Recognize this type of reaction
<p>An alcohol</p> $  \begin{array}{c}  \text{H} \quad \text{H} \\    \quad   \\  \text{H}-\text{C}-\text{C}-\text{OH} \\    \quad   \\  \text{H} \quad \text{H}  \end{array}  \xrightarrow[\Delta]{\text{H}_2\text{SO}_4}  $			
<p>Any alcohol and a halide</p> $  \begin{array}{c}  \text{H} \quad \text{OH} \quad \text{H} \quad \text{H} \\    \quad   \quad   \quad   \\  \text{H}-\text{C}-\text{C}-\text{C}-\text{C}-\text{H} \\    \quad   \quad   \quad   \\  \text{H} \quad \text{H} \quad \text{H} \quad \text{H}  \end{array}  + \text{HI}  $			
<p>A primary alcohol</p> $  \begin{array}{c}  \text{H} \quad \text{H} \\    \quad   \\  \text{H}-\text{C}-\text{C}-\text{OH} \\    \quad   \\  \text{H} \quad \text{H}  \end{array}  + [\text{O}]  $ <p>What is [O]? Give two examples</p>			
<p>A secondary alcohol</p> $  \begin{array}{c}  \text{H} \quad \text{OH} \quad \text{H} \quad \text{H} \\    \quad   \quad   \quad   \\  \text{H}-\text{C}-\text{C}-\text{C}-\text{C}-\text{H} \\    \quad   \quad   \quad   \\  \text{H} \quad \text{H} \quad \text{H} \quad \text{H}  \end{array}  + [\text{O}]  $			
<p>A tertiary alcohol</p> $  \begin{array}{c}  \text{CH}_3 \\    \\  \text{H}_3\text{C}-\text{C}-\text{OH} \\    \\  \text{CH}_3  \end{array}  + [\text{O}]  $			
<p>An alcohol and an alcohol</p> $  \begin{array}{c}  \text{H} \quad \text{H} \\    \quad   \\  \text{H}-\text{C}-\text{C}-\text{OH} \\    \quad   \\  \text{H} \quad \text{H}  \end{array}  + \text{HO}-\begin{array}{c} \text{H} \quad \text{H} \\   \quad   \\ \text{C} \quad \text{C} \\   \quad   \\ \text{H} \quad \text{H} \end{array}  $			
<p>An alcohol and a carboxylic acid</p> $  \text{R}'-\text{OH} + \text{R}-\begin{array}{c} \text{O} \\ // \\ \text{C} \\ \backslash \\ \text{O}-\text{H} \end{array}  $			

## Unit 2, Lesson 13: Homework on Polymers

1. Read pages 81 – 84 and 88 – 92.
2. Define: polymer, monomer.
3. Give three examples of synthetic (man-made) polymers. Identify the monomer from which each synthetic polymer is made.
4. Define addition polymerization. What functional group must the monomer have in order to form an addition polymer?
5. Define condensation polymer. What two types of bonds hold condensation polymers together?
6. Draw an amide bond.
7. What is the common name for a condensation polymer that contains amide bonds (an amine bonded to a carboxylic acid)?
8. What is the common name for a condensation polymer that contains ester bonds (an alcohol bonded to a carboxylic acid)?
9. What type of bond (linkage) holds glucose molecules together to form the starch polymer? (page 90 or 91)
10. On pages 84 – 85, do questions 18, 19, 20a,b,c, 21
11. On page 95 – 96, do questions 1, 2, 3a

### Summary Chart: Functional Groups and their Properties

Type of Compound	Functional Group	Example with Structural Formula & Name	Notes and Properties
Alkane			
Alkene			
Alkyne		$\text{CH}_3-\text{C}\equiv\text{C}-\text{CH}_3$	
Aromatic			
Alkyl Halide			
Alcohol			
Ether			
Primary Amine			
Aldehyde			
Ketone			
Carboxylic Acid			
Ester
