## Unit 7, Lesson 08: The pH of Salt Solutions

Salts are produced when acids and bases react in neutralization reactions.
When soluble salts dissolve in water, they completely dissociate into their ions. If the parent acid or base of the ions are weak acids or weak bases, these ions will react with water and produce $\mathrm{H}_{3} \mathrm{O}^{1+}{ }_{(\text {aq })}$ or $\mathrm{OH}^{1-}(\mathrm{aq})$ ions. Because the ions are reacting with or "splitting water" apart to form hydronium or hydroxide ions, the ions are said to "hydrolyze" (split water apart). The resulting salt solutions will NOT necessarily be neutral. They can be acidic, basic or neutral depending on the salt. The effects of both ions in the salt must be considered in order to determine the pH of a salt solution.

## 1. Salts of strong acids and strong bases: eg. NaBr

a) Look at the positive ion, $\mathrm{Na}^{1+}$

- the parent base of $\mathrm{Na}^{1+}$ is NaOH , which is a very strong base
- Because NaOH is a very strong base, $\mathrm{Na}^{1+}$ is a very weak acid. It is too weak to react with water to produce $\mathrm{H}_{3} \mathrm{O}^{+}$
- Therefore, $\mathrm{Na}^{1+}$ ions do not react with water (do not hydrolyze ) and the presence of $\mathrm{Na}^{1+}$ ions does not affect the pH of a solution
b) Look at the negative ion, $\mathrm{Br}^{1-}$
- the parent acid of $\mathrm{Br}^{1-}$ is HBr , which is a very strong acid
- Because HBr is a very strong acid, $\mathrm{Br}^{1-}$ is a very weak base. It is too weak to react with water to produce $\mathrm{OH}^{1-}$
- Therefore, $\mathrm{Br}^{1-}$ ions do not react with water (do not hydrolyze ) and the presence of $\mathrm{Br}^{1-}$ ions does not affect the pH of a solution

Because neither $\mathrm{Na}^{1+}$ nor $\mathrm{Br}^{1-}$ react significantly with water, the pH of a solution of NaBr is neutral.

## 2. Salts of strong acids and weak bases: eg. $\mathbf{N H}_{4} \mathbf{N O}_{3}$

a) Look at the positive ion, $\mathrm{NH}_{4}{ }^{1+}$

- the parent base of $\mathrm{NH}_{4}{ }^{1+}$ is $\mathrm{NH}_{3}$, which is a weak base (a solution of $\mathrm{NH}_{3}$ is also written $\mathrm{NH}_{4} \mathrm{OH}$ )
- Because $\mathrm{NH}_{3}$ is a weak base, $\mathrm{NH}_{4}{ }^{1+}$ is a relatively strong acid. It will react with water to produce $\mathrm{H}_{3} \mathrm{O}^{+}$

$$
\mathrm{NH}_{4}{ }^{1+}{ }_{(\mathrm{aq})}+\mathrm{H}_{2} \mathrm{O}_{(\mathrm{l})} \rightarrow \mathrm{NH}_{3(\mathrm{aq})}+\mathrm{H}_{3} \mathrm{O}^{1+}{ }_{(\mathrm{aq})}
$$

- Therefore, $\mathrm{NH}_{4}{ }^{1+}$ ions will react with water ( hydrolyze ) to form $\mathrm{H}_{3} \mathrm{O}^{1+}$ which will make the solution acidic
b) Look at the negative ion, $\mathrm{NO}_{3}{ }^{1-}$
- the parent acid of $\mathrm{NO}_{3}{ }^{1-}$ is $\mathrm{HNO}_{3}$, which is a very strong acid
- Because $\mathrm{HNO}_{3}$ is a very strong acid, $\mathrm{NO}_{3}{ }^{1-}$ is a very weak base. It is too weak to react with water to produce $\mathrm{OH}^{1-}$
- Therefore, $\mathrm{NO}_{3}{ }^{1-}$ ions do not react with water (do not hydrolyze ) and the presence of $\mathrm{NO}_{3}{ }^{1-}$ ions does not affect the pH of a solution

Because of the presence of the acidic $\mathrm{NH}_{4}{ }^{1+}$ ion with the neutral $\mathrm{NO}_{3}{ }^{1-}$ ion, the pH of a solution of $\mathrm{NH}_{4} \mathrm{NO}_{3}$ will be acidic.
3. Salts of weak acids and strong bases: eg. $\mathrm{Mg}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2}$
a) Look at the positive ion, $\mathrm{Mg}^{2+}$

- the parent base of $\mathrm{Mg}^{2+}$ is $\mathrm{Mg}(\mathrm{OH})_{2}$, which is a very strong base
- Because $\mathrm{Mg}(\mathrm{OH})_{2}$ is a very strong base, $\mathrm{Mg}^{2+}$ is a very weak acid. It is too weak to react with water to produce $\mathrm{H}_{3} \mathrm{O}^{+}$
- Therefore, $\mathrm{Mg}^{2+}$ ions do not react with water (do not hydrolyze ) and the presence of $\mathrm{Mg}^{2+}$ ions does not affect the pH of a solution
b) Look at the negative ion, $\mathrm{CH}_{3} \mathrm{COO}^{1-}$
- the parent acid of $\mathrm{CH}_{3} \mathrm{COO}^{1-}$ is $\mathrm{CH}_{3} \mathrm{COOH}$, which is a weak acid.
- Because $\mathrm{CH}_{3} \mathrm{COOH}$ is a weak acid, $\mathrm{CH}_{3} \mathrm{COO}^{1-}$ is a relatively strong base. It is strong enough to react with water to produce OH -

$$
\mathrm{CH}_{3} \mathrm{COO}^{1-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}_{(\mathrm{l})} \rightarrow \mathrm{CH}_{3} \mathrm{COOH}_{(\mathrm{aq})}+\mathrm{OH}_{(\mathrm{aq})}^{1-}
$$

- Therefore, $\mathrm{CH}_{3} \mathrm{COO}^{1-}$ ions will react with water ( hydrolyze ) to form $\mathrm{OH}^{-}$which will make the solution basic

Because of the presence of the neutral $\mathrm{Mg}^{2+}$ ion with the basic $\mathrm{CH}_{3} \mathrm{COO}^{1-}$ ion, the pH of a solution of $\mathrm{Mg}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2}$ will be basic.

## 4. Salts of weak acids and weak bases: eg. $\mathrm{NH}_{4} \mathrm{ClO}_{2}$

(This material is not testable. It will be dealt with at university but it follows the same pattern we have been discussing.)

In this situation, both of the ions will hydrolyze (react with) water. The pH of the final solution will depend on the relative strengths of the ions.

- If the $k_{\mathrm{a}}$ of the weak acid is stronger than the $k_{\mathrm{b}}$ of the weak base, then the final solution will be acidic.
- If the $k_{\mathrm{b}}$ of the weak base is stronger than the $k_{\mathrm{a}}$ of the weak acid, then the final solution will be basic.

The parent base of $\mathrm{NH}_{4}{ }^{1+}$ is the weak base, NH 3 (also written $\mathrm{NH}_{4} \mathrm{OH}$ ). Therefore, $\mathrm{NH}_{4}{ }^{1+}$ is a strong enough acid to react with water (hydrolyzes) according to the reaction:
$\mathrm{NH}_{4}{ }^{1+}{ }_{(\mathrm{aq})}+\mathrm{H}_{2} \mathrm{O}_{(\mathrm{l})} \rightarrow \mathrm{NH}_{3(\mathrm{aq})}+\mathrm{H}_{3} \mathrm{O}^{1+}{ }_{(\mathrm{aq})} \quad k_{\mathrm{a}}=\left(1.0 \times 10^{-14} / k_{\mathrm{b}}\right.$ of $\left.\mathrm{NH}_{3}\right)=5.6 \times 10^{-10}$

The parent acid of $\mathrm{ClO}_{2}{ }^{1-}$ is the weak acid, $\mathrm{HClO}_{2}$. Therefore, $\mathrm{ClO}_{2}{ }^{1-}$ is a strong enough base to react with water (hydrolyzes) according to the reaction:
$\mathrm{ClO}_{2}{ }^{1-}{ }_{(\mathrm{aq})}+\mathrm{H}_{2} \mathrm{O}_{(\mathrm{l})} \rightarrow \mathrm{HClO}_{2(\mathrm{aq})}+\mathrm{OH}^{1-}(\mathrm{aq}) \quad k_{\mathrm{b}}=\left(1.0 \times 10^{-14} / k_{\mathrm{a}}\right.$ of $\left.\mathrm{HClO}_{2}\right)=9.1 \times 10^{-13}$

Because the $k_{\mathrm{a}}$ of $\mathrm{NH}_{4}{ }^{1+}$ is greater than the $k_{\mathrm{b}}$ of $\mathrm{ClO}_{2}{ }^{1-}$, the pH of the salt solution will be acidic.
